Q1. How many genes are in this dataset?

There are 38694 genes in this dataset.

Q2. How many 'control' cell lines do we have?

```
n.control <- sum(metadata$dex == "control")
```

There are 4 control cell lines in this dataset.

Extract and summarize the control samples

To find out where the control samples are we need the metadata.

```
control <- metadata[metadata[,"dex"]=="control",]
control.counts <- counts[ ,control$id]
head(control.counts)
```

```

         900.75            0.00          520.50          339.75           97.25
ENSG00000000938
           0.75
```

Q3. How would you make the above code in either approach more robust?

We could make the above code in either approach more robust by not using `rowSums()` and manually dividing it by 4. Instead, we use `rowMeans()` which would give more robust results not matter the sample size.

Q4. Follow the same procedure for the treated samples (i.e. calculate the mean per gene across drug treated samples and assign to a labeled vector called treated.mean)

```
treated <- metadata[metadata[,"dex"]=="treated",]
treated.counts <- counts[ ,treated$id]
treated.mean <- rowMeans(treated.counts)
head(treated.mean)
```

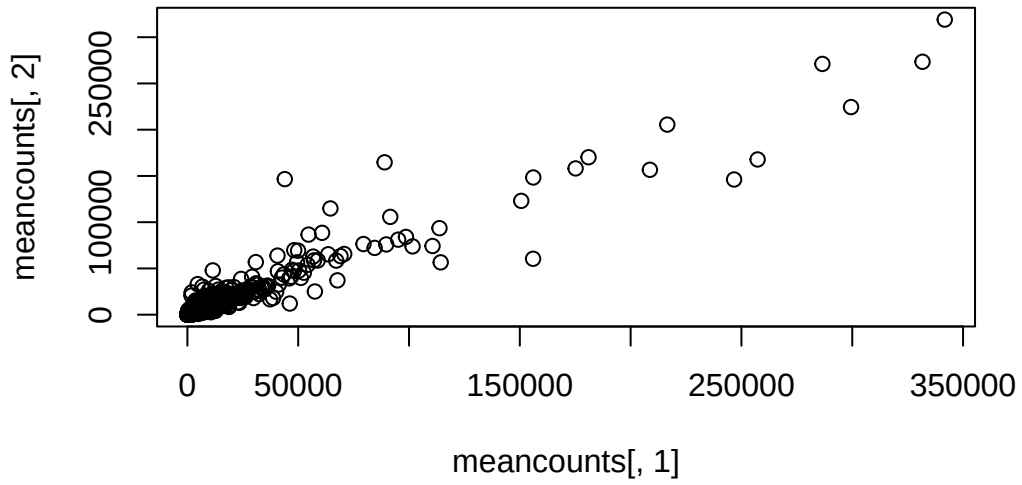
```
ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
         658.00            0.00          546.00          316.50           78.75
ENSG00000000938
           0.00
```

Store these results together in a new data frame called `meancounts`.

```
meancounts <- data.frame(control.mean, treated.mean)
```

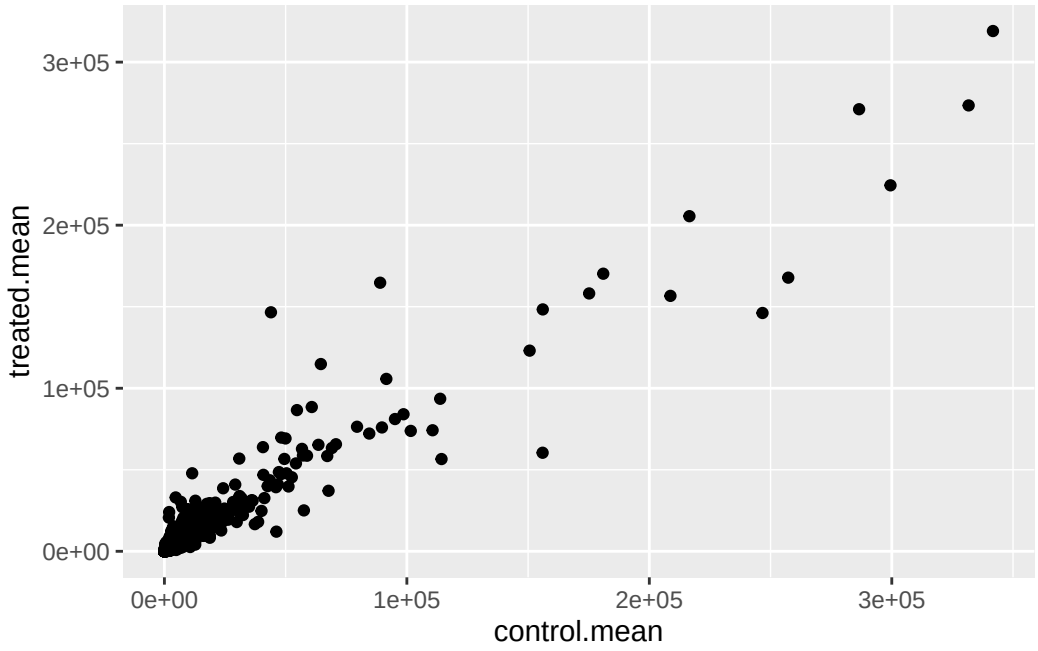
Q5 (a). Create a scatter plot showing the mean of the treated samples against the mean of the control samples. Your plot should look something like the following.

```
plot(meancounts[, 1], meancounts[,2])
```



Q5 (b).You could also use the ggplot2 package to make this figure producing the plot below. What geom_?() function would you use for this plot?

```
library(ggplot2)
ggplot(meancounts, aes(control.mean, treated.mean)) + geom_point()
```

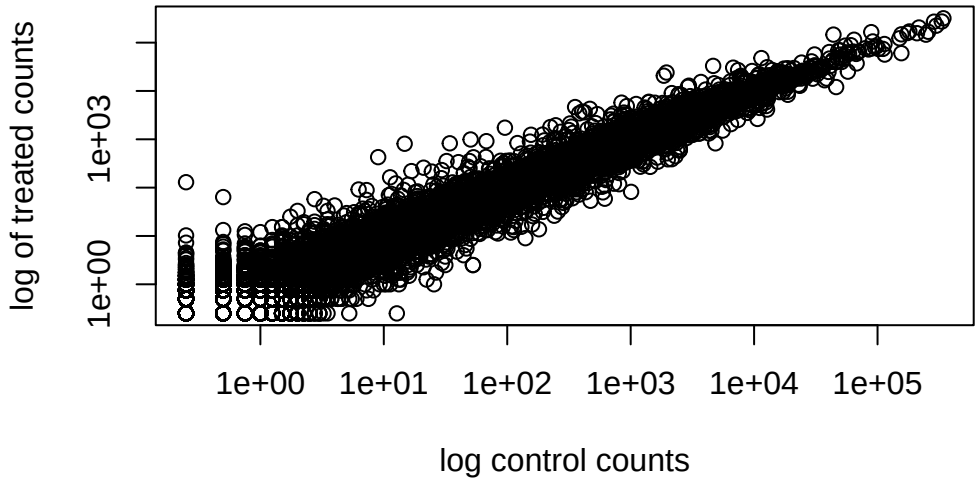


Q6. Try plotting both axes on a log scale. What is the argument to plot() that allows you to do this?

```
plot(meancounts[, 1], meancounts[,2], log="xy", xlab="log control counts", ylab ="log of t
```

```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted
from logarithmic plot
```

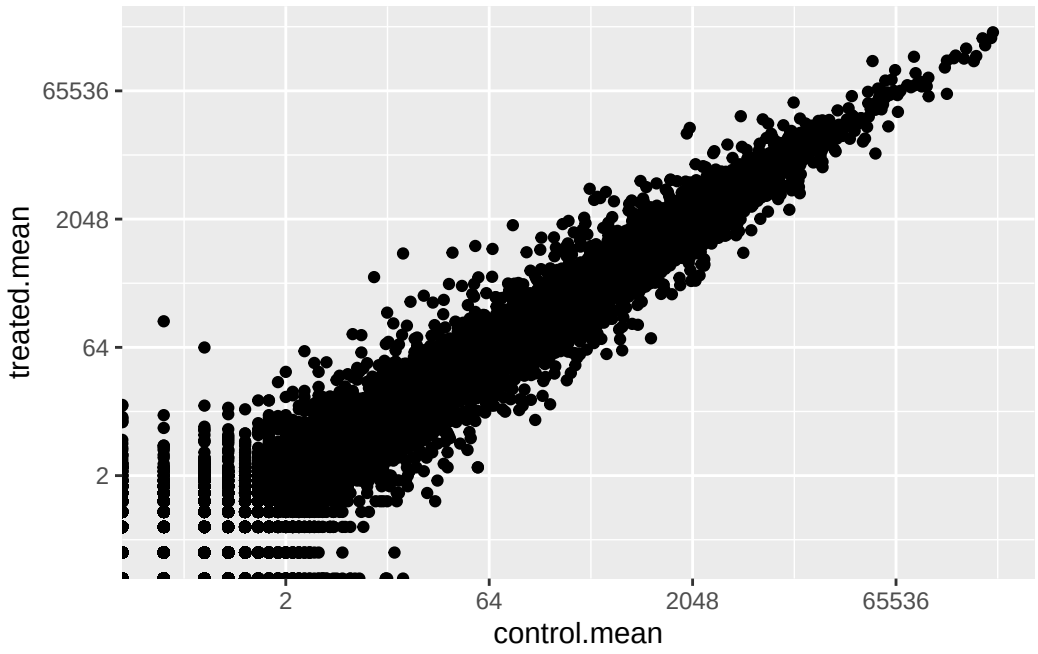
```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted
from logarithmic plot
```



```
ggplot(meancounts, aes(control.mean, treated.mean)) + geom_point() + scale_x_continuous(tr
```

```
Warning: Transformation introduced infinite values in continuous x-axis
```

```
Warning: Transformation introduced infinite values in continuous y-axis
```



This log2 transformation has the nice property where if there is no change the log2 value will be zero and if it doubles log2 value will be 1, and if havles it will be -1.

```
meancounts$log2fc <- log2(meancounts[,"treated.mean"]/meancounts[,"control.mean"])
head(meancounts)
```

```
                control.mean treated.mean      log2fc
ENSG00000000003       900.75       658.00 -0.45303916
ENSG00000000005         0.00         0.00         NaN
ENSG00000000419       520.50       546.00  0.06900279
ENSG00000000457       339.75       316.50 -0.10226805
ENSG00000000460        97.25        78.75 -0.30441833
ENSG00000000938         0.75         0.00        -Inf
```

Q7. What is the purpose of the arr.ind argument in the which() function call above? Why would we then take the first column of the output and need to call the unique() function?

```
head(which(meancounts[,1:2]==0, arr.ind = TRUE))
```

```
                row col
ENSG00000000005   2   1
```

```
ENSG00000004848  65   1
ENSG00000004948  70   1
ENSG00000005001  73   1
ENSG00000006059 121   1
ENSG00000006071 123   1
```

The arr.ind argument will give the names or index of the row where it exists a zero.

```
zero.vals <- which(meancounts[,1:2]==0, arr.ind=TRUE)

to.rm <- unique(zero.vals[,1])
mycounts <- meancounts[-to.rm,]
head(mycounts)
```

```
                control.mean treated.mean      log2fc
ENSG00000000003       900.75       658.00 -0.45303916
ENSG00000000419       520.50       546.00  0.06900279
ENSG00000000457       339.75       316.50 -0.10226805
ENSG00000000460        97.25        78.75 -0.30441833
ENSG00000000971      5219.00      6687.50  0.35769358
ENSG00000001036      2327.00      1785.75 -0.38194109
```

We need to call `unique()` function because there might be multiple zeroes in one row.

A common threshold used for calling something differentially expressed is a log2(FoldChange) of greater than 2 or less than -2. Let's filter the dataset both ways to see how many genes are up or down-regulated.

```
up.ind <- mycounts$log2fc > 2
down.ind <- mycounts$log2fc < (-2)
```

Q8. Using the up.ind vector above can you determine how many up regulated genes we have at the greater than 2 fc level?

```
sum(up.ind)
```

```
[1] 250
```

Q9. Using the down.ind vector above can you determine how many down regulated genes we have at the greater than 2 fc level?

```
sum(down.ind)
```

```
[1] 367
```

Q10. Do you trust these results? Why or why not?

Not fully because we don't really know if these changes are statistically significant.

DESeq2 Analysis

```
# load up DESeq2
library(DESeq2)
```

```
dds <- DESeqDataSetFromMatrix(countData=counts,
                              colData=metadata,

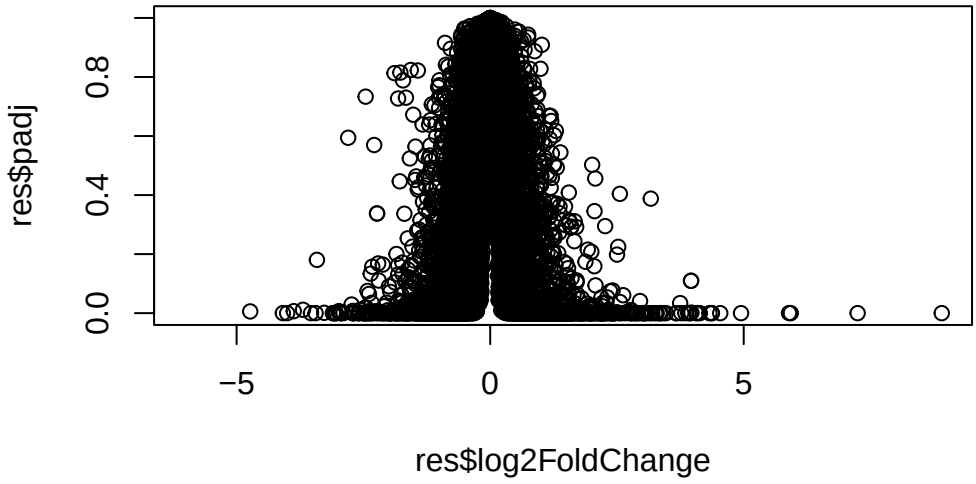
[2] see 'independentFiltering' argument of ?results
```

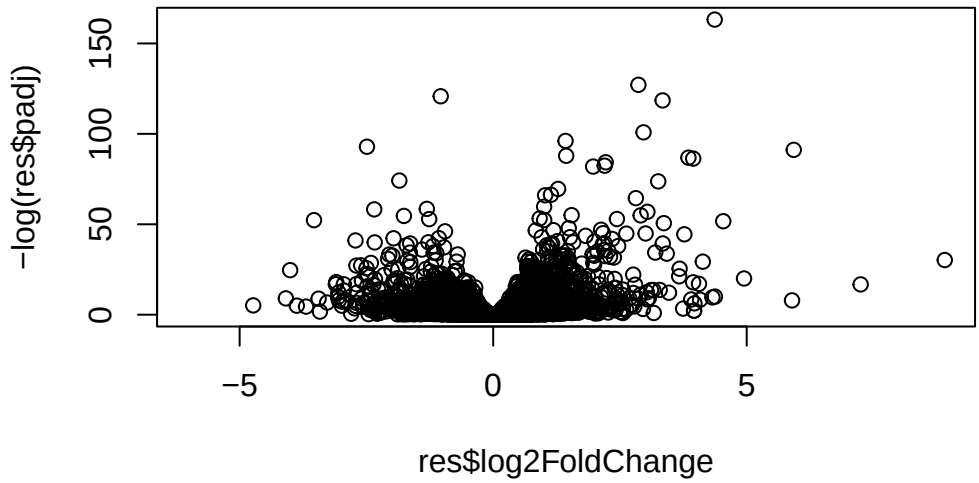
Volcano plot

Make a summary plot of our results.

```
plot(res$log2FoldChange,res$padj)
```



```
plot(res$log2FoldChange,-log(res$padj))
```

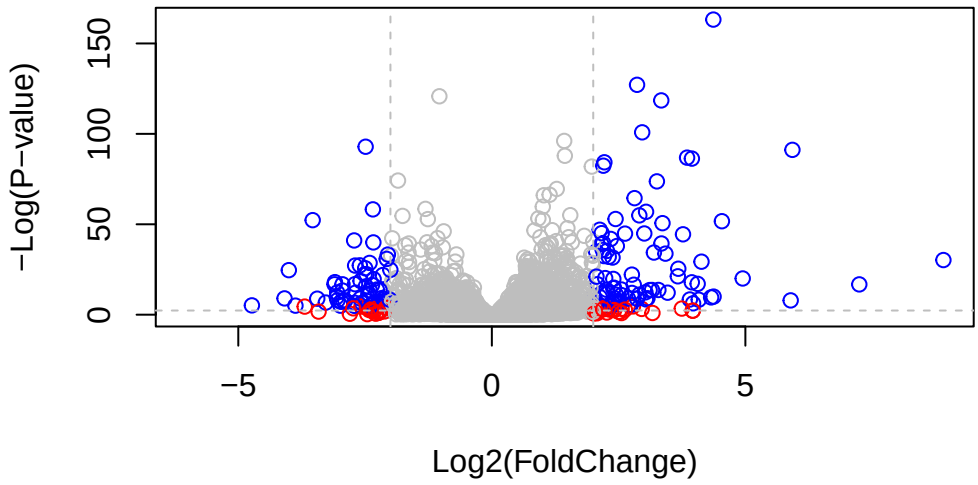


```
# Setup our custom point color vector
mycols <- rep("gray", nrow(res))
mycols[ abs(res$log2FoldChange) > 2 ]  <- "red"

inds <- (res$padj < 0.01) & (abs(res$log2FoldChange) > 2 )
mycols[ inds ] <- "blue"

# Volcano plot with custom colors
plot( res$log2FoldChange,  -log(res$padj),
 col=mycols, ylab="-Log(P-value)", xlab="Log2(FoldChange)" )

# Cut-off lines
abline(v=c(-2,2), col="gray", lty=2)
abline(h=-log(0.1), col="gray", lty=2)
```



We will use one of Bioconductor's main annotation packages to help with mapping between various ID schemes. Here we load the `AnnotationDbi` package and the annotation data package for humans `org.Hs.eg.db`.

```
library("AnnotationDbi")
```

```
Attaching package: 'AnnotationDbi'
```

```
The following object is masked from 'package:dplyr':

    select
```

```
library("org.Hs.eg.db")
```

Look at what types of IDs I can translate between from the `org.Hs.eg.db` package with the `column()` function.

```
columns(org.Hs.eg.db)
```

```

```

The main `gage()` function requires a named vector of fold changes, where the names of the values are the Entrez gene IDs.

```
foldchanges = res$log2FoldChange
names(foldchanges) = res$entrez
head(foldchanges)
```

```
      7105       64102        8813       57147       55732        2268
-0.35070302          NA  0.20610777  0.02452695 -0.14714205 -1.73228897
```

```
keggres = gage(foldchanges, gsets=kegg.sets.hs)
```

```
attributes(keggres)
```

```
$names
[1] "greater" "less"    "stats"
```

Now lets look at the object returned from `gage()`, i.e. our results here:

```
head(keggres$less,3)
```

```
